Identity of *Euprymna berryi* Sasaki, 1929 (Cephalopoda: Sepiolidae)

Takashi OKUTANI and Eiichi HORITA

(Tokyo University of Fisheries, 4-5-7 Konan, Minato-ku, Tokyo 108)

Abstract: As the results of critical observations on fashion of arm sucker enlargement, morphology of tentacular suckers and bodily and spermatophoric proportions, it was concluded that the genus *Euprymna* in the Japanese waters contains two sympatric species, *E. morsei* (Verrill, 1888) and *E. berryi* Sasaki, 1929.

Verrill (1881) described *Inioteuthis Morsei* from Bay of Yeddo (=Tokyo). This species was transferred to the genus *Euprymna* created by Steenstrup (1887) based on morphology of hectocotylus. The name *E. morsei* had been universally used for Japanese *Euprymna* until Sasaki (1913) separated them into two species, *E. morsei* and *E. similis*. Later, he (1929) erected *E. berryi* for *E. morsei* auct. and made *E. similis* synonymous with *E. morsei* sensu Sasaki. Because of such slight differences, some subsequent authors (e.g. Adam 1954, Okutani 1979) considered that these two would be conspecific.

This paper re-evaluates some conventional characters and gives a critical consideration of these two nominal species with a relief of other criteria and allometry.

Before going further, we extend our sincere gratitude to Mr. Kenjiro Konno and Dr. Susumu Segawa, Tokyo University of Fisheries, for their warm helps and advices rendered during the present study. We owe Prof. Kengo Soma of the same university for his instruction of SEM techniques. Many specimens were collected with helps of Mr. Yasuyuki Koike and the staff of Banda Marine Laboratory as well as Mr. Akira Maekawa and other students of our laboratory.

Materials and Methods

The total number of *Euprymna* was 124. But, only mature 42 males (7.00-35.30 mm DML) were used for the study; 54 females (7.20-53.35 mm DML) and smaller immature specimens were examined freely for reference. Among these

Fig. 1. Measurements of *Euprymna* ミミイカ類の測定方法

- A. Dorsal view. DML: Dorsal mantle length; FL: Fin length; HL: Head length; HW: Head width.
 B. Ventral view. ALI: First arm length; FW: Fin width; MW: Mantle width; VML: Ventral mantle width.
 C. Spermatophore. AbL: Aboral part length; I-IL: Intermediate first part length; I-IIL: Intermediate second part length; I-IIIL: Intermediate third part length; OL: Oral part length; SL: Spermatophore length; SW: Spermatophore width.

42 males, 7 were from the Pacific coast of Ibaraki and Chiba Prefectures, 33 were from Tokyo Bay-Sagami Bay area and 2 from near Yaku Island, south of Kyushu (Table 1). Twenty-nine of them were dip-netted under nightlight at Banda Marine Laboratory or from catches of a trap-net fixed near Takano-shima, Tateyama Bay, by Mr. A. Maekawa who used these animals for feeding behavior study. Other specimens were taken by either beam-trawl or larva net

on board the R/V *Soyo-Maru*, Tokai Regional Fisheries Research Laboratory, and deposited in the National Science Museum, Tokyo. The collecting seasons were extended to various months of years (Appendix Table 1).

The measurements on both animal and spermatophore were illustrated in Fig. 1. The abbreviations and measurements mostly follow Roper and Voss (1983). However, some are different from theirs: FW (fin width) is not a width all across both lobes of fins together with mantle, but a transverse length of each odd lobe. On spermatophore, ABL (aboral part length), I-I to IIII (lengths of intermediate 1st to 3rd part) and OL (oral part length) were measured. The indices of spermatophoric measurements are percentage of SL (spermatophore length) not of DML.

Results

1. *Morphological characters:*

On 42 males of the present specimens, the following description can be given: The mantle is dome-shaped, slightly depressed dorso-ventrally, wider anteriorly than posteriorly. The anterior dorsal margin is fused with the head in distance of $\frac{1}{2}$ to $\frac{2}{3}$ of MW. The ventral margin is shallowly emarginated leaving blunt lateral lobes on both sides. The fins are oval and attached on the lateral mantle slightly anteriorly to the middle and have rather deep incision at anterior attachment. The head is also depressed dorso-ventrally, HL is about half of ML, but HW is almost equal to MW. The eyes are situated slightly dorsally and posteriorly with oval orbit. No olfactory papilla is present.

The funnel is conical tapering towards the tip reaching to the base of the arm IV. The funnel locking cartilage is elongate oval in shape with shallow groove. The mantle locking cartilage is a slender ridge slightly shorter than twice the length of groove of funnel cartilage. The funnel organs are consisted of inverted V-shaped dorsal pad and a pair of pyriform ventral pads. They are flat except a mesial fleshy ridge running along the central axis of the dorsal pad.

The funnel valve is inverted heart-shaped and situated at halfway between the anterior tip of dorsal pad and free margin of the funnel.

Arms are unequal with a formula of II, III, IV, I (12 specimens) followed by II, III, I, IV (9 spec.) and III, II, IV, I (8 spec.). The longest arm exceeds DML. Interbrachial web is most prominent between arms III and IV, but very slight between arms I's, I and II, and II and III. No web is present between arms IV's. Arms are roundish aborally and rather flat orally. A low aboral swimming keel is present on all arms, but that of the arm IV is situated more ventrally as a continuation of the interbrachial web. Four rows of conical pedicels are present on the oral surface. Suckers are situated in an oblique position on the tops of these pedicels. The suckers are spherical in shape except those on the modified portion of the hectocotyized arm. The marginal suckers are always larger than mesial suckers. There are some enlarged suckers but the fashion of enlarge sucker distribution shows specific difference (see next section).

Hectocotyization is affected on the left arm I, which is shorter and thicker than the counter arm and is usually reflected dorsally. In this arm, one or two suckers at 2nd to 3rd of the ventral row from the base are lacking, instead sucker pedicels of them are swollen into one or two large conical papillae. Sucker pedicels of distal half of this arm are also transformed into conical papillae that are packed together forming a parisade-like structure. The proximal part of sucker cup is extended over the opening which is circular and has 15 triangular sharp teeth along the $\frac{2}{3}$ of inner margin.

Tentacle stalk is slightly flattened orally. The club is only slightly wider than the stalk and curled ventrally with a pointed tip which reflected dorsally. There is a ventral web extending backwards to the one-third of the stalk. Suckers are very small and crowded. Two types of suckers exhibit specific difference (see next section). The chitinous area of the suckers consists of three zones encircling the opening. The innermost zone is consisted of 19–25 pieces of fan shaped blocks, the intermediate one, 19–25 pieces of septangonal or octangonal blocks, and the outermost zone, 38–51 pieces of polygonal blocks that are alternating with 2–3 former pieces per one block. These blocks are ornamented with minute pores and low pegs superficially. The central opening is rather tubular and connects to the inner cavity. The sucker pedicels are cylindrical distally but thickened basally.

Radula has seven teeth which are all sharply pointed and bend forwards. The outer marginal is longer than the others and overlaps inner marginal.

A saccular light organ is present on both sides of the ink sac. The "penis" is apparent between the renal opening and the posterior end of the mantle cavity. Spermatophore is thicker towards the aboral part and tapers towards the oral part. Intermediated part is divisible into three parts.

Fig. 4. Tentacle suckers 触腕吸盤

A, B. *Euprymna morsei*, 20.80mm DML. A, $\times 700$; B, $\times 210$

C, D. *E. berryi*, 25.90mm DML. C, $\times 620$; D, $\times 770$

2. Specific difference in morphological characters:

Out of 42 male specimens, 29 specimens ranging from 7.00 mm to 18.75 mm DML have enlarged suckers only on the ventral rows of arms. In the arm I, marginal suckers are slightly larger than mesial ones. On the arm II to IV, enlarged suckers become apparent from the proximal 3rd or 4th suckers. This type is identifiable to be *E. morsei* (Fig. 2).

In 13 specimens ranging from 13.30 to 35.30 mm DML, both dorsal and ventral rows have enlarged suckers. The arm I is similar to that of the preceding type, but arm III has several enlarged suckers from the proximal 5th to 8th. In the arms II and IV, enlargement occurs from the proximal 2nd to 4th suckers

on both dorsal and ventral rows. This character well agrees with *E. berryi* (Fig. 3).

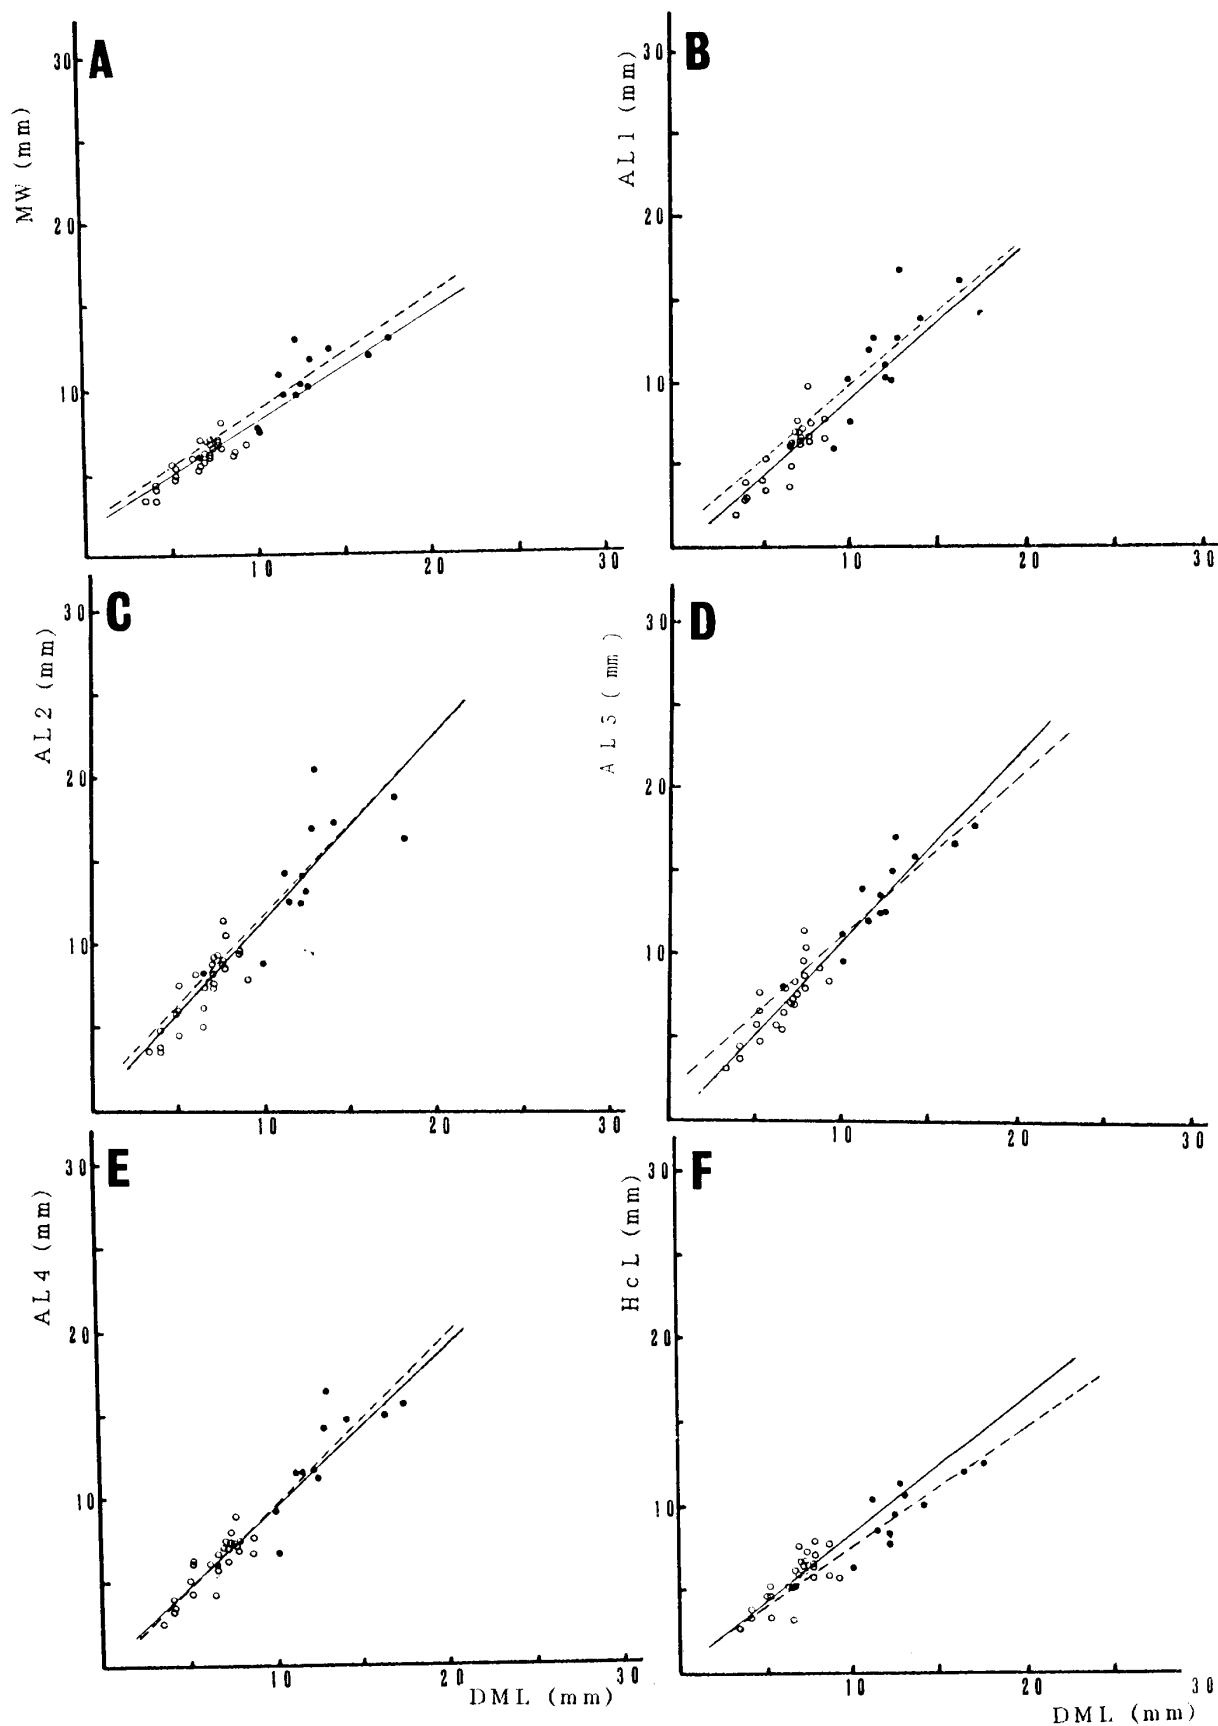

As was described by Sasaki (1929), *E. morsei* has cup-shaped or spherical tentacle suckers, while *E. berryi* has goblet-shaped or smoking-pipe-shaped suckers (Fig. 4).

The former one is more frequent in smaller specimens, while the latter is so

present study. Forty-three spermatophores of both species were also measured (Appendix table 2) and five spermatophoric indices were computed (Table 4).

Among contemporary indices, both species do not exhibit a spectacular difference between them. Only FLI and HLI show slightly over 10% difference. In connection with this, female *E. morsei* does not differ from male in these indices, but female *E. berryi* slightly differs from male in ALI and ALII. Coefficients for DML-MW, DML-ALI to IV and DML-HcL are quite high ($R > 0.80$) in both species, but a considerable difference between two was detected

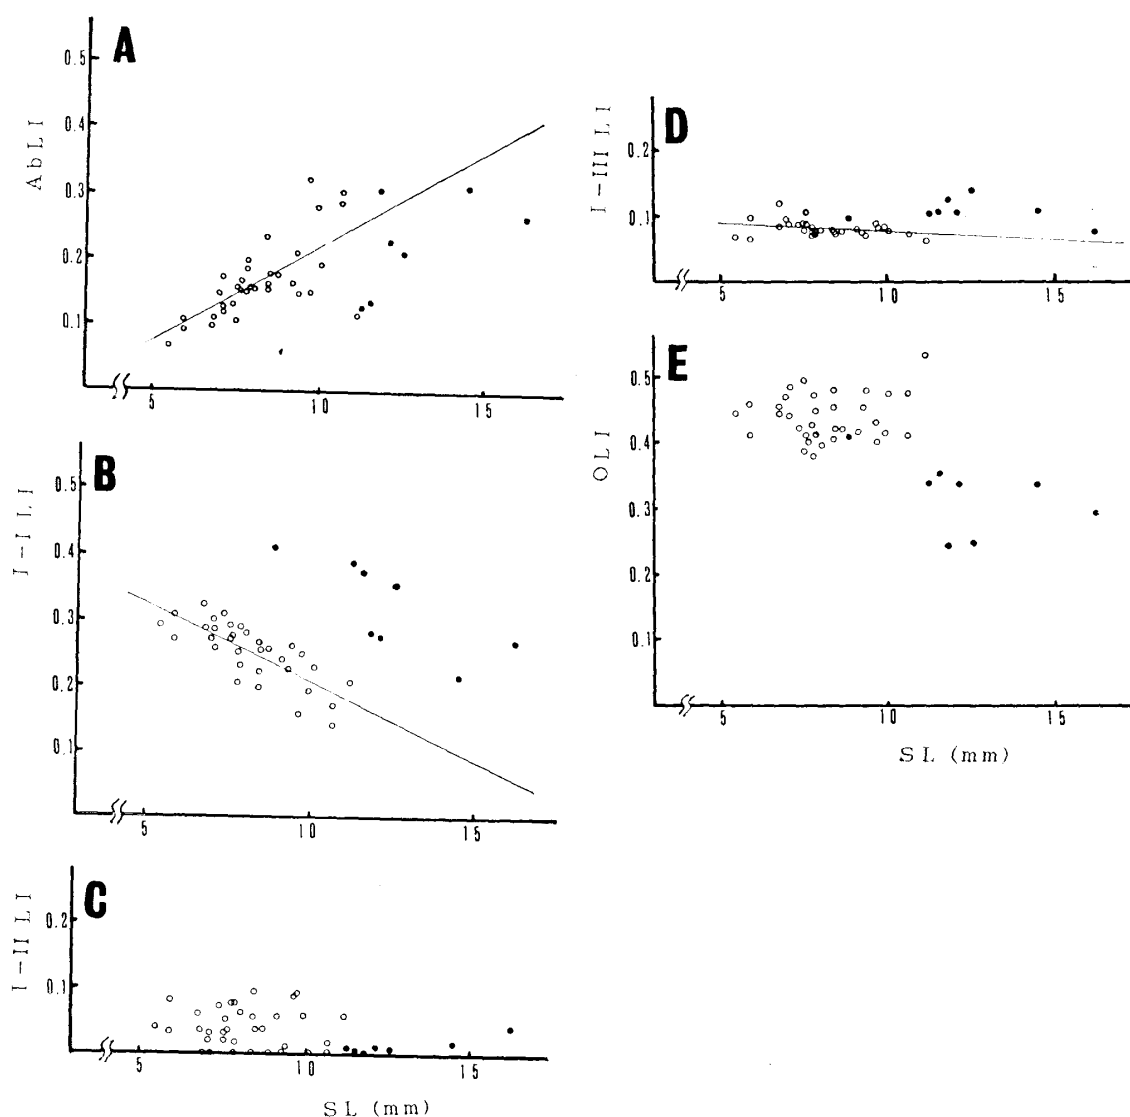

Fig. 9. Relationship between spermatophore length and aboral part length index (A), intermediate 1st part length index (B), 2nd part length index (C), 3rd part length index (D), and oral part length index. 精莖長に対する精莖各部の比率
Open circles and solid line: *E. morsei*; filled circles; *E. berryi*. For definition of index, see footnote of Table 4.

in DML-HcL (Fig. 5). The correlation between ALI-IV and ASC of each arm of *E. morsei* is abandoned at $\alpha=0.05$ significant level (Fig. 6). While, that in *E. berryi* was still low ($R=0.60-0.76$). HcL-HcSC was not so significant in both species (Fig. 7).

Significant differences are apparent in spermatophoric indices (Table 4), namely, AbLI (18.4%), I-II LI (21.7%), I-III LI (64.9%) I-III LI (23.4%) and OLI (27.0%), respectively.

Regression coefficient was computed for spermatophoric proportions in *E. morsei* (Table 5). Number of specimen of *E. berryi* in hand was so small that no statistical test was made for comparison, but the difference from

E. morsei is visually presented (Figs. 8 & 9).

Discussion

In spite of the fact that Verrill's original description of "*Iniotteuthis Morsei*" was very brief, the name *morsei* had been applied to Japanese species by Appellöf (1886), Hoyle (1886), Steenstrup (1887), Ortmann (1888), Wülker (1910) and Berry (1912) before Sasaki (1913) first separated Japanese *Euprymna* into two species, *E. mosei* and *E. similis*.

In the original description in Japanese of *E. similis*, Sasaki (1913) emphasized the following two characters with which it was separable from *E. "morsei"*. (1) In the arm II, 10–12 enlarged suckers are present only on the ventralmost (outer) row among four series. These enlarged suckers begin not from the base but several suckers distally. The suckers of dorsal outer row are slightly larger than mesial ones. (2) In the arm III and IV, enlarged suckers are counted 10 or more unlike *E. "morsei"* in which only limited number of central suckers are enlarged. He also mentioned that the tentacle suckers are short and its length equals to the width, while those in *E. "morsei"* have a smoking-pipe like appearance.

Later, Sasaki (1929) assured that the tentacular suckers of the type specimen of *E. morsei* were identical with those of *E. similis*, which was then synonymized. From this standpoint, Sasaki (1929) created a new species *E. berryi* that is characterized by different fashion of sucker enlargement and shape of tentacle suckers. Adam (1954), however, claimed that the shape of tentacle suckers may transform from globular (or short cylindrical) to elongate (or smoking-pipe shape), suggesting that *morsei* and Sasaki's *berryi* would be synonymous.

According to our critical observation on fully mature males of *Euprymna* from Japanese waters, we could recognize validity of criteria (such as fashion of arm sucker enlargement and morphology of tentacular suckers), used by Sasaki (1913). Allometrical examination on six items (Fig. 5) indicates that both two are so close that they have very similar bodily proportions. However, sucker counts of some arms (Fig. 6) and some spermatophoric proportions (Fig. 9) clearly separate *E. morsei* and *E. berryi*.

要 約

佐々木 (1913) は日本のミミイカ属 *Euprymna* には2種あり, *E. morsei* (Verrill, 1881) と *E. similis* n. sp. とした。*E. similis* が前種と異なる点は, 第2腕の吸盤が腹外列のみ拡大していること, 第3・4腕に拡大吸盤が10以上あること, 及び触腕吸盤が円筒杯形である (前種では煙管の雁首状) ことなどであった。のち (1929), 彼は *E. morsei* の模式標本の触腕吸盤を観たところこれは上記の *E. similis* と同一であることが判り, 却ってそれまで多くの著者が *E. morsei* と呼んでいた種の多くが別種であると判定し *E. berryi* の名を創設した。

しかしAdam (1954)などは触腕吸盤の形態差などを種内変異の域を出ないと考え、*E. berryi* は *E. morsei* の異名とした。

今回、各地から採集されたミミイカ属の成熟雄42個体について腕吸盤の拡大様式、触腕の吸盤形態のみならず体各部の相対比率、腕長と吸盤数、精莖各部位の比率等につき詳しく検討を行った結果、Sasaki (1929) の見解を支持する結論を得た。

すなわち、日本周辺に産するミミイカ属は *E. morsei* (Verrill, 1881) ミミイカと *E. berryi* Sasaki, 1929 ニヨリミミイカ (新称) の2種がほぼ同所的分布をしている。
